

## Channelopathies associated with ion channels localized in **brain**

- Voltage-gated  $\text{Ca}^{++}$  channels

Disorder	Clinical characteristics	Type of mutation	Notes
Familial Hemiplegic Migraine (FHM)	<ul style="list-style-type: none"> <li>• <b>Migraine attacks</b> <ul style="list-style-type: none"> <li>- typically last one to three days.</li> <li>- During such episodes, patients experience severe headaches and vomiting.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Several mutations in a human <math>\text{Ca}^{2+}</math> channel have been identified in families with FHM, each having different clinical symptoms.</li> <li>• A mutation in the <b>pore-forming region</b> of the channel produces hemiplegic migraine with progressive cerebellar ataxia.</li> <li>• Other mutations cause only the usual FHM symptoms.</li> </ul>	How these altered $\text{Ca}^{2+}$ channel properties lead to migraine attacks is not known.
Episodic Ataxia type 2 (EA2)	<ul style="list-style-type: none"> <li>• Recurrent attacks of abnormal <b>limb movements</b> and severe <b>ataxia</b>. <ul style="list-style-type: none"> <li>- sometimes accompanied by vertigo, nausea, and headache</li> <li>- usually attacks are precipitated by emotional stress, exercise, or alcohol</li> <li>- last for a few hours.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Truncation of <math>\text{Ca}^{2+}</math> channels at various sites, which prevents the normal assembly of <math>\text{Ca}^{2+}</math> channels in the membrane.</li> </ul>	
X-Linked Congenital Stationary Night Blindness (CSNB)	<ul style="list-style-type: none"> <li>• Nightblindness, decreased visual acuity, myopia, nystagmus, and strabismus.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Incomplete type</b> of CSNB is caused by mutations producing <b>truncated <math>\text{Ca}^{2+}</math> channels</b>. <b>Abnormal retinal function</b> may arise from decreased <math>\text{Ca}^{2+}</math> currents and neurotransmitter release from photoreceptors.</li> </ul>	<ul style="list-style-type: none"> <li>• recessive retinal disorder</li> <li>• <b>Complete CSNB</b> causes retinal rod photoreceptors to be <b>nonfunctional</b>.</li> <li>• <b>Incomplete CSNB</b> causes <b>subnormal</b> (but measurable) functioning of both rod and cone photoreceptors</li> </ul>

- Voltage-gated K<sup>+</sup>channels

Disorder	Clinical characteristics	Type of mutation	notes
benign familial neonatal convulsion (BFNC),	<ul style="list-style-type: none"> <li>• frequent <b>brief seizures</b></li> <li>• commencing within the first week of life</li> <li>• disappearing spontaneously within a few months.</li> </ul>	<ul style="list-style-type: none"> <li>• The mutation has been mapped to at least two voltage-gated K<sup>+</sup> channel genes.</li> </ul>	A reduction in K <sup>+</sup> current flow through the mutated channels probably accounts for the <b>hyperexcitability</b> associated with this defect.
episodic ataxia <b>type 1</b> (EA1),	<ul style="list-style-type: none"> <li>• brief episodes of <b>ataxia</b></li> </ul>		Mutant channels inhibit the function of other, non-mutant K <sup>+</sup> channels and may produce clinical symptoms by impairing action potential repolarization.

- Voltage-gated Na<sup>+</sup>channels

Disorder	Clinical characteristics	Type of mutation	notes
generalized epilepsy with febrile seizures (GEFS)	<ul style="list-style-type: none"> <li>- begins in infancy</li> <li>- usually continues through early puberty</li> </ul>	mapped to two mutations: <ul style="list-style-type: none"> <li>• one on chromosome 2 that encodes an <math>\alpha</math>-subunit for a voltage-gated Na<sup>+</sup> channel</li> <li>• the other on chromosome 19 that encodes a Na<sup>+</sup> channel <math>\beta</math>-subunit.</li> </ul>	These mutations cause a slowing of Na <sup>+</sup> channel inactivation which may explain the neuronal <b>hyperexcitability</b> underlying GEFS.
